Livestock operations, mainly poultry and swine, are increasing in size and impact in the Southern Minnesota sugar beet growing area. Many sugar beet producers own or have interest in these operations; thus have manure available to use on their fields. Manure research data concludes that manure has a positive effect on crop production from its effects on soil nutrient availability and soil physical properties. A concern has been raised about the effect of late season nitrogen mineralized from the manure on sugar beet quality. Grower observations indicate better growth in fields that have had manure applied. With the large amount of manure available, the question has changed from whether to use manure but when in the sugar beet crop rotation should manure be applied to minimize quality concerns and realize benefits? Turkey manure has a considerable amount of litter in it, thus slowing initial release of poultry manure-N. The implication of the manure-N release is critical, especially to sugar beet growers. Therefore, recommendations need to be evaluated with sugar beets. This research project has been designed to: 1) determine when in a three-year rotation, should turkey litter be applied and 2) determine nitrogen fertilizer equivalent of turkey litter applied two and three years in advance of sugar beet production.

Materials and Methods

To meet the objectives of this experiment, the first of three sites was established near Raymond, Minnesota in the fall of 2006. A second site was established in the fall of 2007 near Olivia, Minnesota and a third site was established near Bird Island in 2009. The Bird Island site was lost because of an errant manure application by the cooperator.

The Raymond site was cropped to soybean in 2007. Turkey manure was applied fall 2006 and soybean grain yields were harvested by a plot combine and soil samples taken in the fall of 2007. The treatments for the second year were applied to the first site near Raymond in the fall of 2007 with corn grown in 2008. The corn was harvested, soil samples taken, and the third year treatments were applied late fall 2008 and sugar beet was grown in 2009.

The second site near Olivia, Minnesota had the first manure treatment applied in the fall of 2007 with soybean grown in 2008. The soybeans were harvested with a research combine, soil samples taken, and the second year’s treatments were applied fall 2008. Corn was grown in 2009 and hand harvested for grain yield fall 2009. After corn harvest, soil samples were taken and the third year treatments were applied and sugar beet will be grown in 2010.

At each site of this study there were five replications of the treatments listed in Table 1. Turkey litter treatments of 3 and 6 tons per acres were applied 2 and 3 years ahead of sugar beet production in the three year rotation of soybean/corn/sugar beet. This rotation is the most common rotation in the Southern Minnesota Sugar Cooperative growing area. Treatment 5 is the check treatment for the whole experiment while treatments 8 and 15 are checks for different parts of the rotation. Treatments 6 through 14 are the N fertilizer rates plus the two turkey litter rate applied the fall before the sugar beet production year. During the corn production year, 120 lb N per acre will be applied for treatments 6 through 14. This is the current U of MN N guideline for corn following soybean. In the soybean production year, grain yield was measured with a research combine. Soil samples were taken in fall to a depth of 4 feet and analyzed for nitrate-N while soil samples to a 6 inch depth were analyzed for phosphorous, potassium, organic matter, and pH. The year 2 manure and fertilizer treatments were applied in the late fall. Corn grain was hand harvested in the fall. Similar to year 1 soil samples were taken. The year 3 treatments were applied late fall of year 2. Root yield and quality were determined in the fall. In each of the production years, optimum production practices for pests control and nutrient management besides nitrogen were used.

Results and Discussion

Raymond Site:

Soybean grain yields where significantly increased by the application of manure in 2007 at the Raymond site, Table 3. This increase was small. There were no differences in grain yield between 3 and 6 tons of turkey litter application. Soil samples were taken after the soybean production year in the fall of 2007. The application of 3 and 6 tons of turkey litter, fall 2006, increased the soil residual nitrate-N and soil test P in the sample taken fall 2007, Table 4.

Corn grain yields in 2008 were measured at the Raymond site, Table 5. The only significant difference in corn grain yield was between the check, with no N fertilizer or turkey litter applied and the corn grain yield from the rest of the treated plots. There were no differences between yields from the 120 pounds N per acre as urea fertilizer and the turkey litter treatments from applied either Fall 2006 of Fall 2007, Table 4. In the Fall of 2008, soil nitrate-N was increase over the check in plots that were treated with
6 tons of turkey litter fall 2006 or fall 2007. The 3 tons of turkey applied in fall 2006 or fall 2007 had similar soil nitrate-N values as the check.

Sugar beets were planted in 2009 with N rate treatments and 3 and 6 turkey litter applications made fall 2008. The root yield, extractable sucrose per ton, extractable sucrose per acre, and revenue for the turkey litter treatments are reported in Table 6 while the statistical analysis is reported in Table 7. Root yield was increased with the use of litter application. The increase was greatest with the fall 2008 litter application. This application was confounded with an application of 120 pounds of fertilizer N per acre. The sugar beet root yield greater with 6 tons litter per acre applied compared to the 3 tons per acre when the litter was applied fall 2007. Sugar beet quality, as measured by the extractable sucrose per ton of processed sugar beet was not affected by the manure treatments. Because of the lack of response in sugar beet quality, extractable sucrose per acre and revenue was affected by the litter treatments the same as root yield was.

To compare litter treatments with fertilizer, a nitrogen rate study was conducted within the litter treatments, Table 8. There was a significant response to nitrogen application at the Raymond, MN site in 2009 for root yield, extractable sucrose per acre, and revenue. Sugar beet quality was not affect by N.
fertilizer application. The optimum nitrogen rate was 90 pounds per acre. The residual nitrate-N in the surface 4 feet was 40 pounds per acre. With both soil nitrate-N and fertilizer N, this would make the optimum of 130 pounds per acre. The optimum fertilizer application was similar statistically to the best litter application for revenue. This would suggest that the time of turkey litter application in the sugar beet rotation is not important at this location. Remember that this observation is based on one location in one year!

Corn was grown in 2009 with treatments added of 120 pounds N per acre and 3 and 6 tons turkey litter applied fall 2008. Corn grain yields from 2009 are reported in Table 10. There was a significant increase in grain yield over no nitrogen from the application of turkey litter and nitrogen fertilizer in 2009. The 120 pounds of N per acre as urea and the 6 tons of turkey litter per acre applied fall 2008 had the greatest grain yields of 218 bushels per acre. Statistically, there was no difference in grain yield between the 2007 and 2008 turkey litter applications. Each year, the 6 ton per acre application produced greater grain yields than the 3 ton per acre application. This site will be planted to sugar beet in 2010.

Table 10. Corn grain yields as affected by the application of 120 pounds N per acre, 3 and 6 tons of turkey litter in fall 2007, and 3 and 6 tons of turkey litter in fall 2008 at Olivia, Minnesota in 2009.
